

Level Building Tools Documentation

Important notes:

- Open the tool with ALT + G or in the Tools menu
- In general, you do not need to have colliders on your objects. Level Building Tools works based on MeshFilter Bounds. For Surface operations such as Project and Clone, you do need to have colliders on your target objects.

The rotation tool will rotate your object by the desired angle in random or nonrandom directions, and it will do it between 1 and the amount of times set on "rotation count". This way you can achieve random results or more predictable results, depending on your settings.

Snap rotation to 90 degrees

Make a spiral shape

The scale tool allows you to scale the selected objects randomly within a minimum and a maximum scale. It can be further customized with the distribution weight so that you can pick the ratio of smaller to larger objects.

Make fewer large objects

Equal amount of small and large objects

Scatter allows for fine control of randomization in order to spread your objects in various ways. Useful in combination with Project, in order to place random debris or vegetation.

Stack aligns your objects based on their AABB (axis aligned bounding box) based on their meshfilters and lines them up on an axis of your choice, with the option to add an extra offset for each item.

Projection allows you to either move objects in a direction until they hit a collider, or to snap objects onto a collider. This tool also applies random rotations on the selected axis.

Clone allows you to copy objects onto any Collider in the world, with alignment options. The object will also be randomly rotated on it's primary axis, which you can select from the dropdown. Objects to be cloned can be either selected in the scene or in the asset browser.

To keep your scene clear, you can also lock a transform to keep your objects parented under.

More documentation is available in each tool as tooltips when you hover over specific buttons and properties.
